LOOKOUT POINT RESERVOIR

LOOKOUT POINT RESERVOIR

Khan et al. 2012

Romer et al. 2015

LOOKOUT POINT RESERVOIR

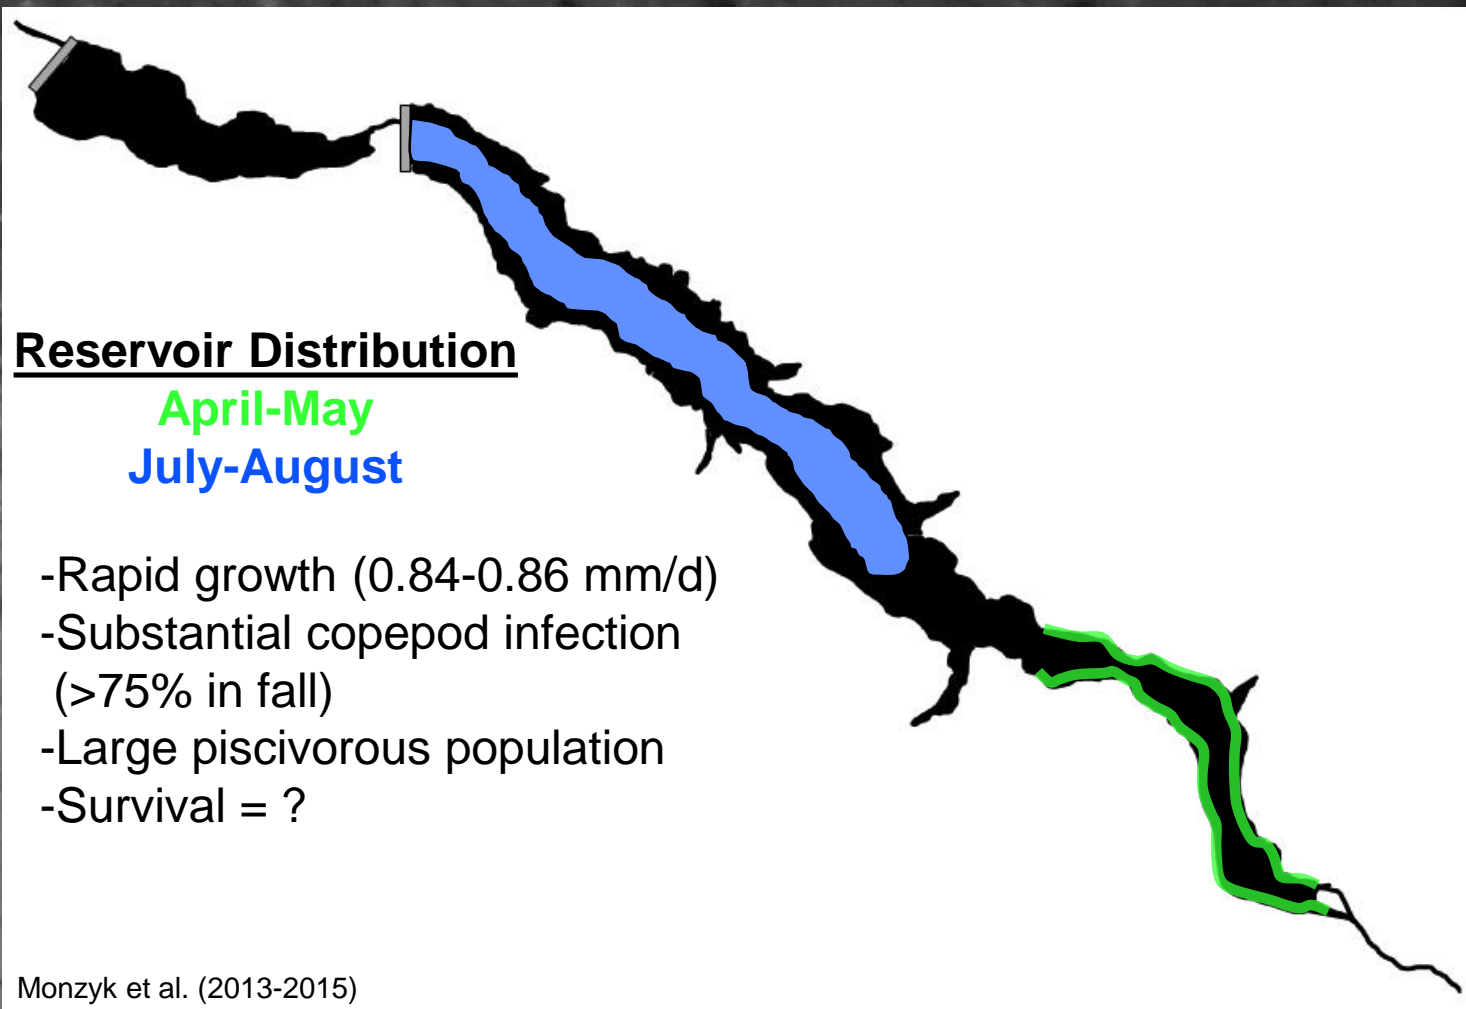

Reservoir Distribution

April-May

July-August

- Rapid growth (0.84-0.86 mm/d)
- Substantial copepod infection (>75% in fall)
- Large piscivorous population
- Survival = ?

Monzyk et al. (2013-2015)

SURVIVAL STUDIES

Common for smolt-sized fish

- Acoustic, radio, and PIT tags
- Reach, passage, and route-specific estimates
- Numerous models and analytical techniques

Challenging for fry-sized fish

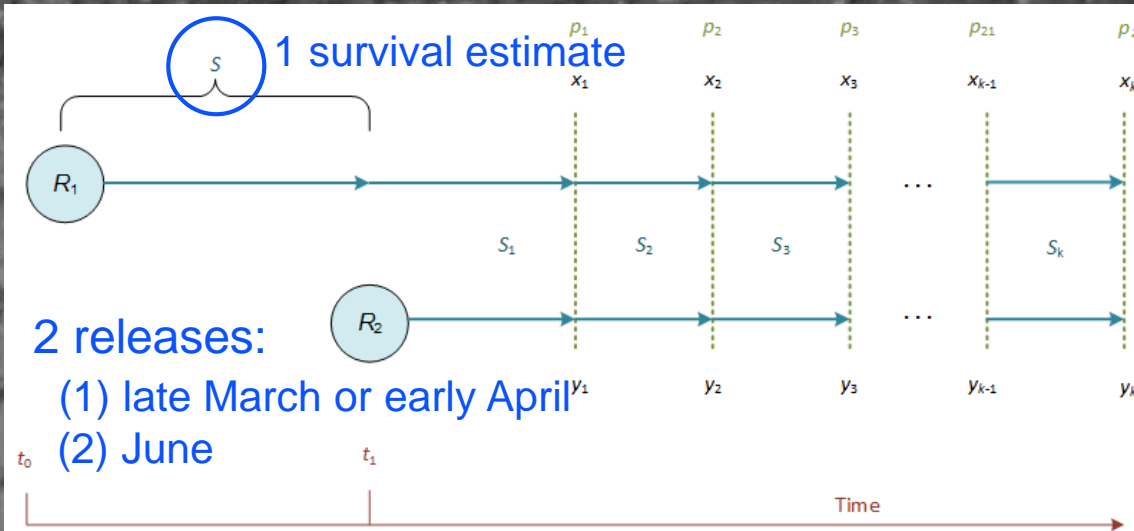

- Batch marking
- Some models designed
- Not field proven

FRY SURVIVAL MODELS

Models have been developed

- Skalski et al. 2009, Skalski 2015
- Staggered Release-Recovery Model

Keywords: external marks, internal marks, mark-recapture, survival estimation, tagging

INTRODUCTION

Small fish represent both the early life stages of many species and the adults of other species. Measuring the survival of small fish is important for effective management of many productive populations (e.g., Pacific salmonids, *Oncorhynchus* spp.), Lepidoptera, and avian species. Considerations make it imperative that survival studies be carefully designed and conducted. Electronic tags (e.g., acoustic, radio, satellite) are commonly used on larger fish for estimating survival and recruitment, stock assessment, evaluating movements, and assessing alternative management practices. For smaller fish (<60-mm fork length), the logistics of marking and conducting release-recapture studies is more difficult and precision. Fewer tagging options are available and tagging and handling effects are often intensified relative to larger fish. Furthermore, survival estimation methods are more dependent on tag choice than for larger fish. The result is a relative lack of precise survival information through early life stages for small fish in general.

For example, vast amounts of information were cited on the survival of anadromous Pacific salmonids between small fall-migrating and adult spring returns arising from Puget Sound Integrated Trout-piper (PTI) tags (e.g., Provench et al. 1990, Skalski et al. 1996, Smith et al. 2002, Buchanan and Skalski 2007), radio tags (Skalski et al. 2001), and acoustic tags (Pinsky et al. 2007). However, these tag technologies are typically not applicable for small juvenile salmonids because emergence from the gravel and seaward migration, life stage related to acuity by some salmonid biologists. Fry may be relatively stationary, or they migrate upstream or downstream to feed. At some point, the anadromous species will migrate to downed seaward migration. The inability to tag very small fish with existing electronic

2.4 Model Assumptions

Assumptions of this paired release-recovery model include the following:

1. All fish act independently.
- 2. Both release groups share the same recovery probabilities (p_i) and intra-period survival probabilities (S_i) after the second release occurs (i.e., θ_i).
3. Sample sizes R_1 and R_2 are known without error.
4. Recovery numbers are correctly reported and assigned to the correct release group.
5. Fish do not lose their tags.

INTRODUCTION

Small fish represent both the early life stages of many species and the adults of other species. Measuring the survival of small fish is important for effective management of many protected populations (e.g., Pacific salmonids, *Oncorhynchus* spp.) (Legel, ethical, and economic considerations make it imperative that survival studies be carefully designed and conducted). Electronic tags (e.g., acoustic, radio, satellite) are commonly used on larger fish for estimating survival and recruitment, stock assessment, evaluating movements, and assessing alternative management practices. For smaller fish (<60-mm fork length), the logistics of marking and conducting release-recovery studies is more difficult and precision. Fewer tagging options are available.

and tagging and handling effects are often minimized relative to larger fish. Furthermore, survival estimation methods are more dependent on tag choice than for larger fish. The result is a relative lack of precise survival information through early life stages for small fish, in general.
For example, vast amounts of information now exist on the survival of anadromous Pacific salmonids between small out-migrating and adult spring returns arising from Passive Integrated Transponder (PIT) tags (e.g., Przewice et al. 1990; Skalski et al. 1996; Smith et al. 2002; Buchanan and Skalski 2007), radio tags (Skalski et al. 2001), and acoustic tags (Pinsky et al. 2007). However, these tag technologies are typically not applicable for small juvenile salmonids between emergence from the gravel and seaward migration, a life stage relevant to us by some salmon biologists. Fry may be relatively stationary, or they might experience 0-dimensional to 1-d. At some point, the anadromous species will engage in directed seaward migration. The inability to tag very small fish with existing electronic

FRY SURVIVAL MODELS

PBT *N*-Mixture Model

- Modified *N*-mixture model
- Requires 1 release group
- PBT used to mark fish

FRY SURVIVAL MODELS

PBT *N*-Mixture Model

Release

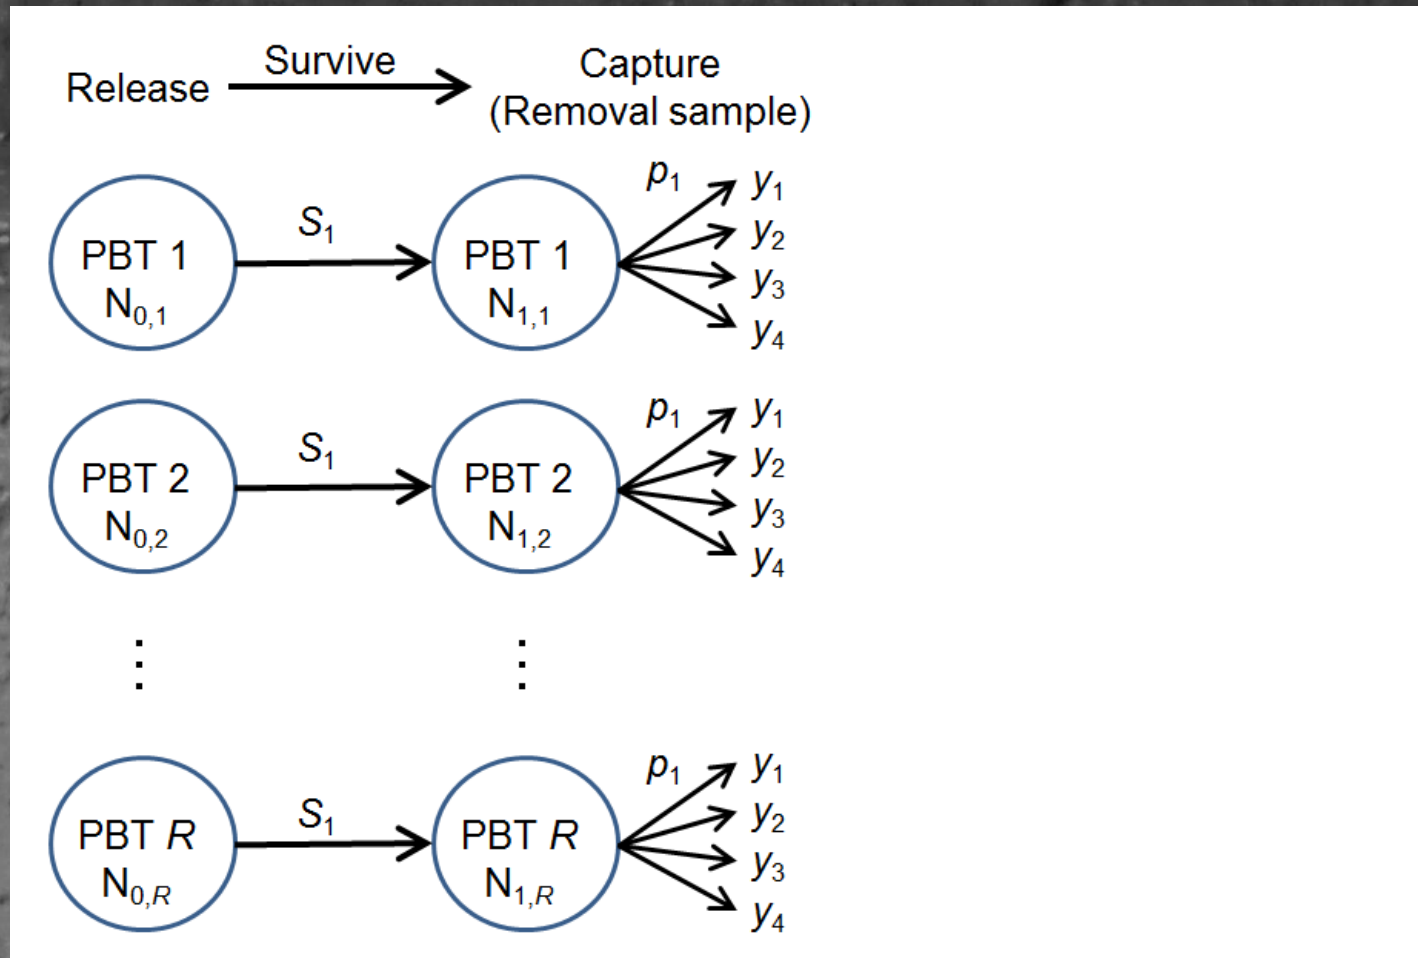

⋮

FRY SURVIVAL MODELS

PBT N-Mixture Model

PBT N-MIXTURE MODEL

Can Parameters Be Estimated?

- Low capture probabilities expected (1-2%)
- Simulation experiments conducted
 - 75,000 fish with 40 PBT marks
 - Monthly sampling: 4 months
- Can't estimate unique p and S for every month
 - p is too low
- Can fit simpler models
 - Constant S or p for consecutive months
 - S as a function of covariates
 - Time
 - Fish size

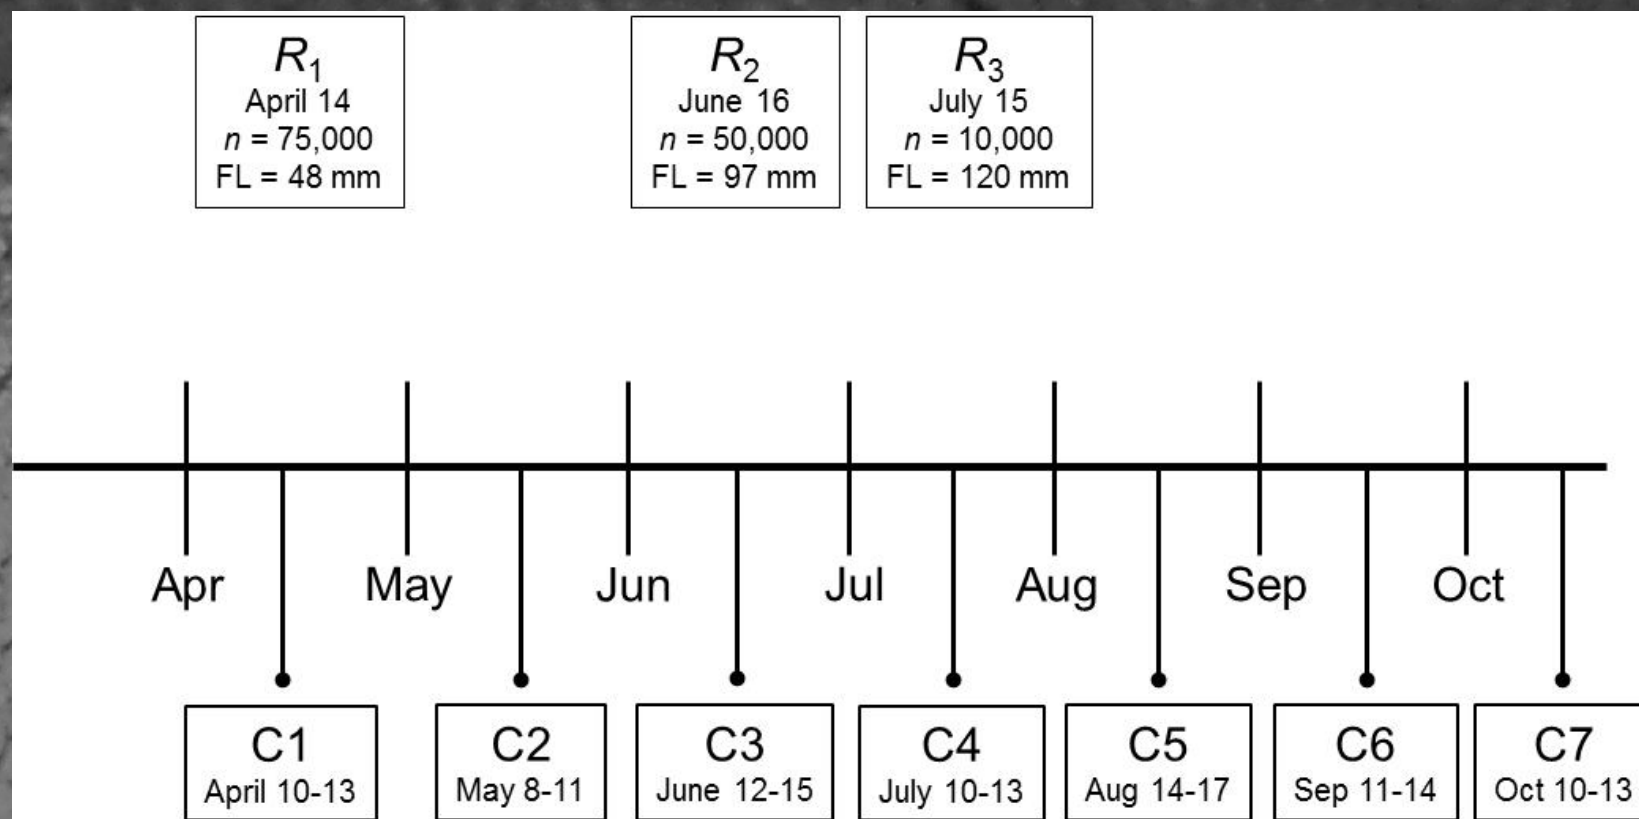

PBT N-MIXTURE MODEL

Can Parameters Be Estimated?

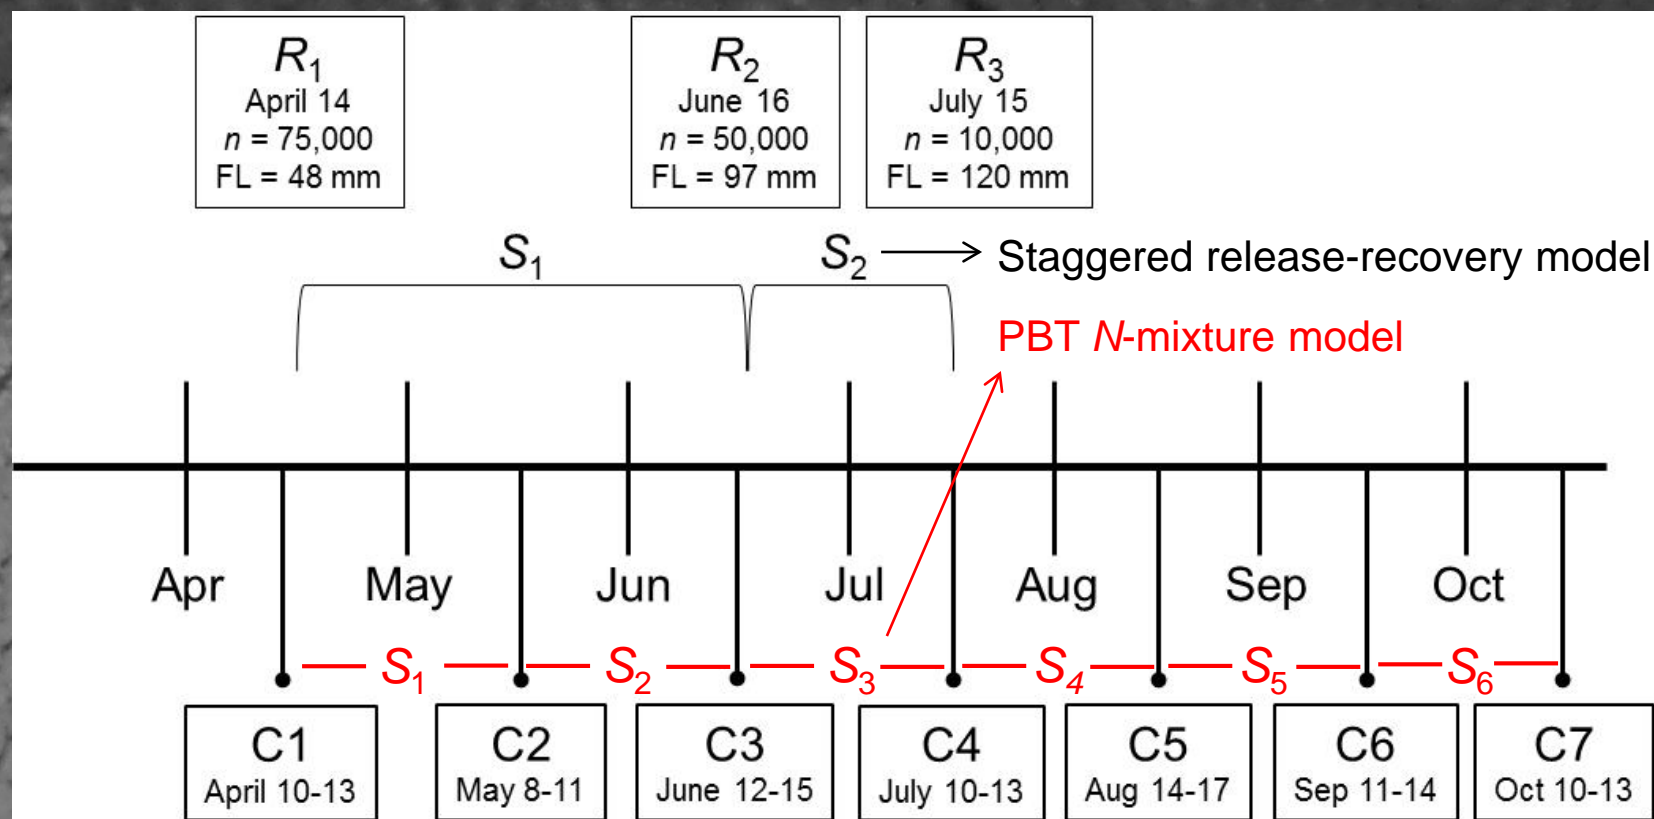

FIELDWORK IN 2017

- Release 3 groups of fish
- Conduct monthly sampling in reservoir

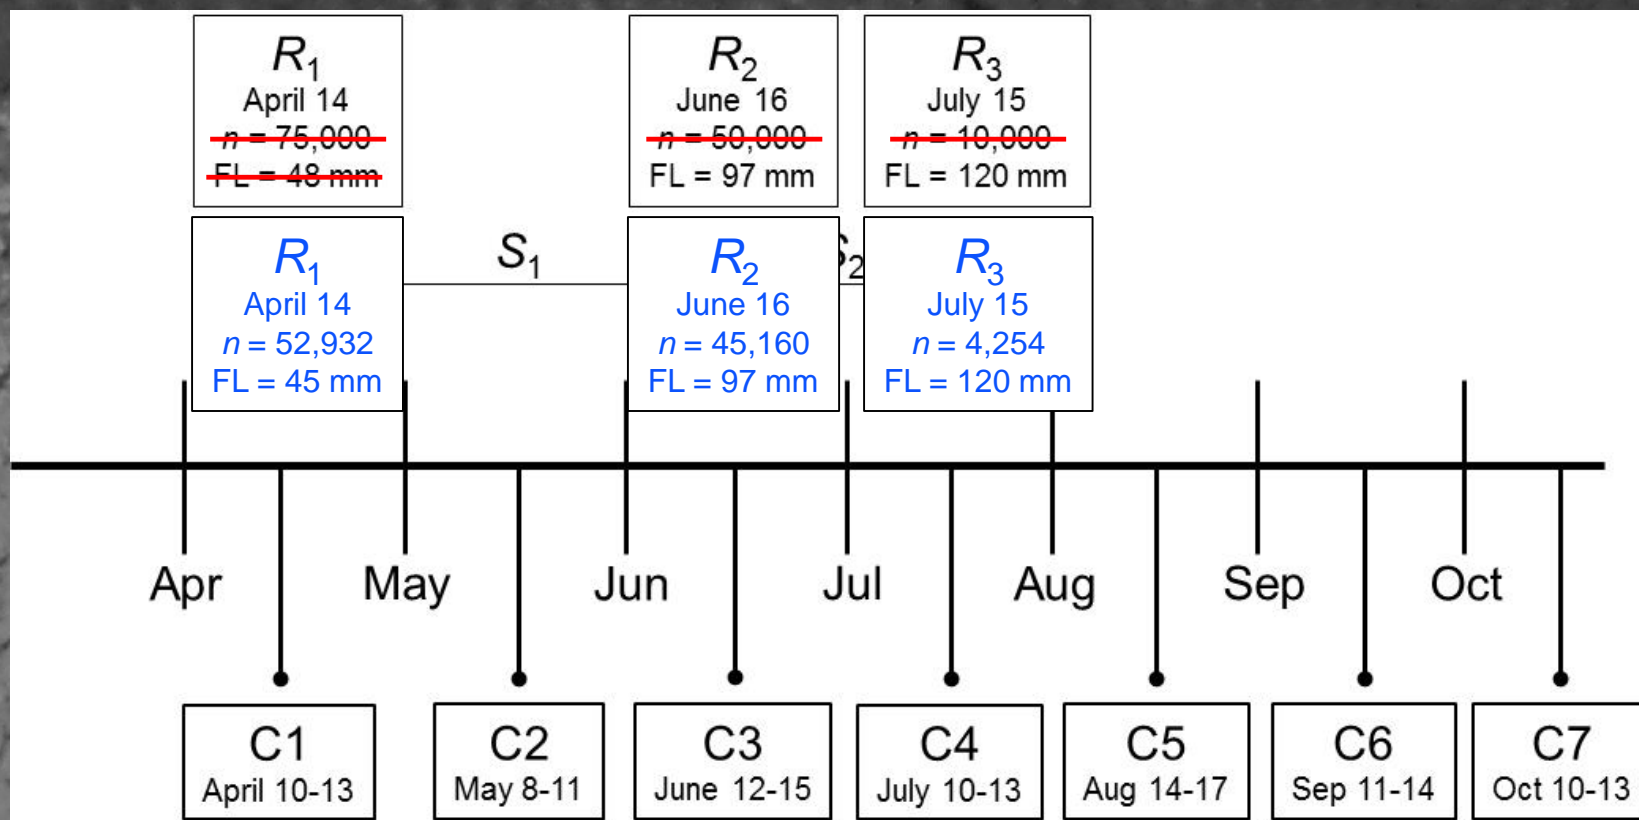

FIELDWORK IN 2017

- Release 3 groups of fish
- Conduct monthly sampling in reservoir

FIELDWORK IN 2017

- Release 3 groups of fish
- Conduct monthly sampling in reservoir

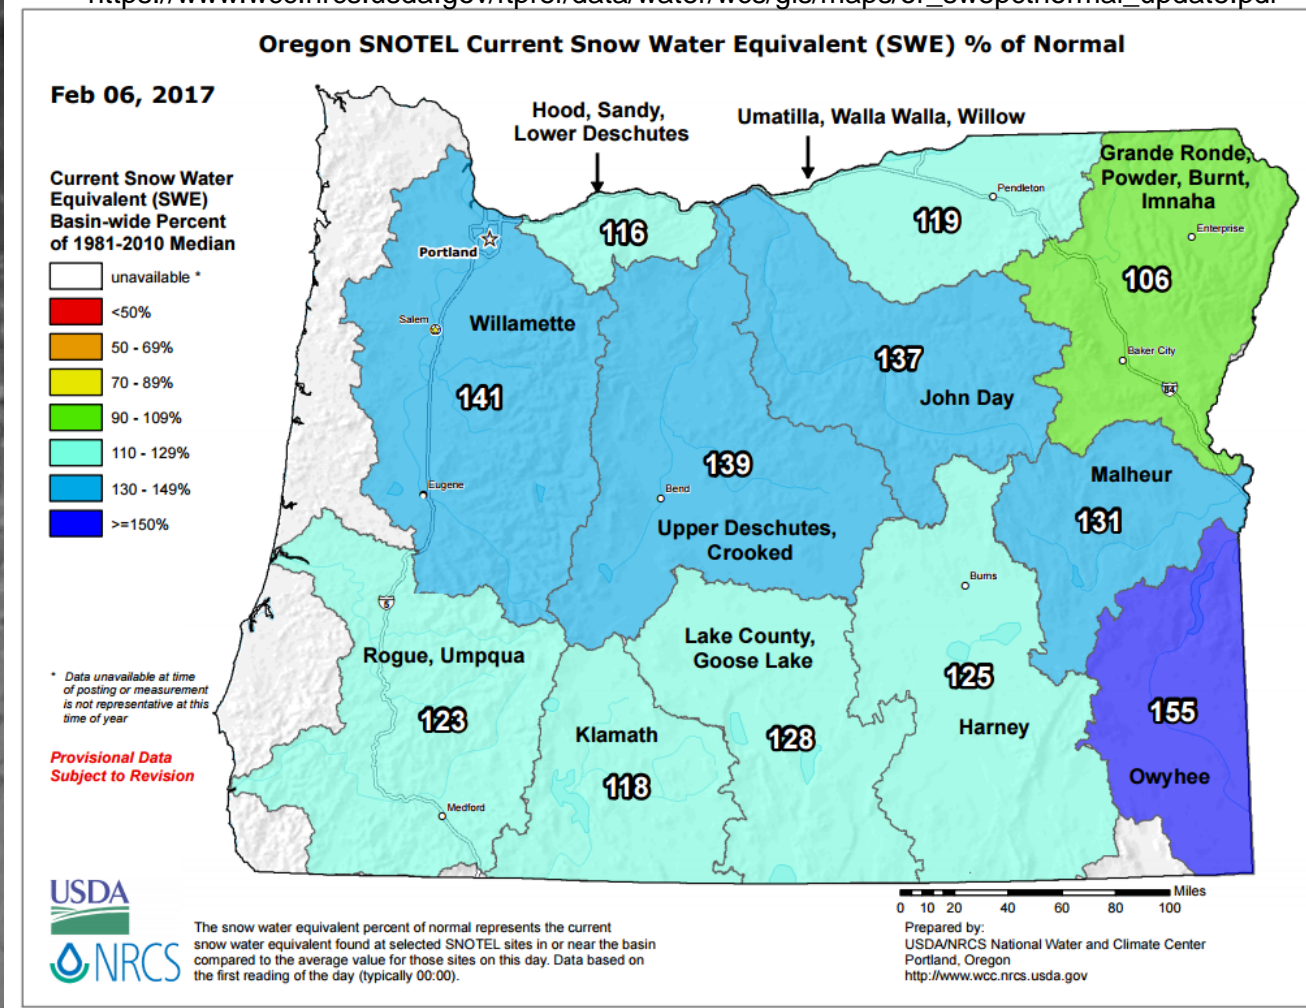

FIELDWORK IN 2017

- Release 3 groups of fish
- Conduct monthly sampling in reservoir
 - 4 sampling days/month
 - 40 “sets”/day
 - Floating box traps, Oneida Lake traps, gill nets
 - Other techniques possible including beach seines and electrofishing

MURPHY'S CONTRIBUTION

https://www.wcc.nrcs.usda.gov/ftpref/data/water/wcs/gis/maps/or_swepctnormal_update.pdf

SUMMARY

- 2 study designs will be evaluated
 - Both conceptually sound, neither field tested
 - Side-by-side testing will be insightful
 - 2017 is a “pilot” study
 - Learning curve for fish releases
 - Unprecedented sampling effort planned
 - Study designs adaptations occurring
